$$\sum_{i=1}^{n} i = \frac{n(n+1)}{2} \qquad \qquad \sum_{i=1}^{n} i^2 = \frac{n(n+1)(2n+1)}{6} \qquad \qquad \sum_{i=1}^{n} i^3 = \frac{n^2(n+1)^2}{4}$$

1.1.6 Another Interpretation

Evaluate $\int_{0}^{1} x^{2} dx$ exactly using midpoint Riemann sums.

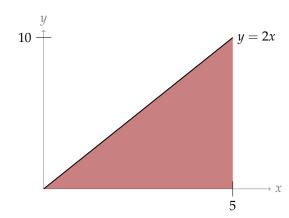

Let's see some special cases where we can use geometry to evaluate integrals without Riemann sums.

A car travelling down a straight highway records the following measurements:

Time	12:00	12:10	12:20	12:30	12:40	12:50	1:00
Speed (kph)	80	100	100	90	90	75	100

Approximately how far did the car travel from 12:00 to 1:00?

The computation

$$distance = rate \times time$$

looks a lot like the computation

$$area = base \times height$$

for a rectangle. This gives us another interpretation for an integral.

Let x(t) be the position of an object moving along the x-axis at time t, and let v(t) = x'(t) be its velocity. Then for all b > a,

$$x(b) - x(a) = \int_{a}^{b} v(t) dt$$

That is, $\int_a^b v(t) dt$ gives the *net distance* moved by the object from time a to time b.
